

MoneyTor — Stock Trading Platform

WORK IN PROGRESS

June 2026 — Ongoing · Full-Stack Web App · React · Vite · Tailwind CSS

Anshumaan Sai Patnaik

Project status: MoneyTor is in active development. The public-facing marketing site is largely built; the authenticated trading dashboard is scaffolded, and the backend is planned but not yet implemented. This report describes the current state and intended direction.

Overview

MoneyTor is an in-progress full-stack stock trading platform, modelled on a modern discount brokerage. The vision is two connected experiences: a public marketing site where prospective users learn about the product, pricing, and support, and a private, authenticated dashboard where logged-in users manage orders, holdings, positions, and funds.

It is the most ambitious project in this collection and is being built incrementally. The front-end foundation is in place; the data layer and live trading features are the next major phase of work.

Current Status

The work so far breaks down into three clear stages of completion:

Built — public marketing site

The public site is a multi-page React application with a shared header and footer and its own routing. It currently includes a landing page (hero, products, integrations, pricing, and education sections), plus dedicated About, Product, Pricing, and Support pages and a 404 route. The pages use real, domain-accurate content — for example, the pricing page lays out a detailed breakdown of brokerage and statutory charges — and are styled responsively with Tailwind CSS and DaisyUI.

Scaffolded — trading dashboard

The authenticated dashboard exists as a separate React application with its own routing already mapped out for the core sections — dashboard, orders, holdings, positions, funds, and apps — along with a sidebar/top-bar shell. These routes are wired up but currently render placeholder content; the actual screens are still to be built.

Planned — backend & live data

The server side has not been started yet. The roadmap includes user authentication, a database for accounts and portfolios, integration with market-data sources for live prices, and the APIs that will power the dashboard's orders, holdings, and funds views.

Technology Stack

React

Component-based UI for both the public site and the dashboard.

Vite	Build tooling and dev server for each front-end app.
React Router	Client-side routing across the marketing pages and dashboard sections.
Tailwind CSS + DaisyUI	Utility-first styling and ready-made UI components for a responsive layout.
Backend (<i>planned</i>)	Server, database, authentication, and market-data integration — to be added in the next phase.

Architecture & Approach

The defining structural decision is the split into **two independent front-end applications** — a *public* app and a *protected* app — rather than one combined site. This cleanly separates the open marketing pages from the authenticated trading area: the two can be developed, built, and eventually deployed independently, and the protected app can later sit behind an authentication boundary without entangling it with the public site.

Within each app the code is organised by page, with each page composed of small section components (for example, the landing page is assembled from separate hero, products, pricing, and education sections). This keeps individual files focused and makes the larger pages easy to rearrange. Shared elements like the header and footer live at the top level and are reused across routes.

The immediate next steps are to flesh out the dashboard screens against placeholder data, then stand up the backend and connect the two — at which point MoneyTor moves from a front-end prototype to a working full-stack platform.
